There is a growing trend toward the use of endoscopic surgery in colonic resection procedures because of its reported advantages. However, in most cases endoscopic colonic anastomosis still is performed with stapled techniques. We evaluated the safety and efficacy of colonic anastomosis in a porcine model using endoscopic submucosal dissection with either a flexible or a rigid stapler. Fourteen pigs were randomly assigned to one of two groups. After division of the distal colon, the left side of the colon was anastomosed using either the simple end-to-end anastomosis with a flexible bar or with a rigid stapler. Efficacy was assessed macroscopically and by measuring tissue hydroxyproline content. There was no difference in anastomotic integrity between the two groups, and no anastomotic leaks were observed in the course of this study. Hydroxyproline content in colonic tissue was similar for both groups. The use of flexible bar to perform endoscopic colonic anastomosis in a porcine model appears to be as safe and effective as the use of rigid stapling.[Correlation of Clinical and Radiographic Assessments in Orthopedic Patients]. The objective of this study was to investigate the correlation between clinical and radi 82157476af
